This special issue entitled “Soft and hard tissue regeneration” will cover both periodontal and implant therapies. Regenerative periodontal treatment goal is to restore functional periodontal support offering a valuable treatment alternative even for teeth with large periodontal destruction, which may be successfully treated and maintained in health for long periods. In most cases where teeth are extracted for periodontal reasons, implant therapy will demand large bone augmentation procedures. Lack of sufficient bone volume may prevent placement of dental implants. In extreme cases, large bone reconstruction is indispensable before implant placement can be performed. Although, most bone grafts are only able to fill and maintain a space, where bone regeneration can occur (“osseointegrative”), the ideal bone graft will also promote osseous regeneration (“osseoinductive”). Several bone augmentation procedures have been described, each, presenting advantages and shortcomings. Success of bone augmentation procedures depends on the presence of bone forming cells, primary wound closure over the augmented area, space creation and maintenance where bone can grow and proper angiogenesis of the grafted area. Factors that influence the choice of the surgical technique are the estimated duration of surgical procedure, its complexity, cost, total estimated length of procedure until the final rehabilitations may be installed and the surgeons’

experience. This special issue will have a definite clinical orientation, and be entirely dedicated to soft and hard tissue regenerative treatment alternatives, both in periodontal and implant therapy, discussing their rationale, indications and clinical procedures. Internationally renowned leading researchers and clinicians will contribute with articles in their field of expertise.

An up-to-date account of the interplay between optimization and machine learning, accessible to students and researchers in both communities. The interplay between optimization and machine learning is one of the most important developments in modern computational science. Optimization formulations and methods are proving to be vital in designing algorithms to extract essential knowledge from huge volumes of data. Machine learning, however, is not simply a consumer of optimization technology but a rapidly evolving field that is itself generating new optimization ideas. This book captures the state of the art of the interaction between optimization and machine learning in a way that is accessible to researchers in both fields.

Optimization approaches have enjoyed prominence in machine learning because of their wide applicability and attractive theoretical properties. The increasing complexity, size, and variety of today's machine learning models call for the reassessment of existing assumptions. This book starts the process of reassessment. It describes the resurgence in novel contexts of established frameworks such as first-order methods, stochastic approximations, convex relaxations, interior-point methods, and proximal methods. It also devotes attention to newer

themes such as regularized optimization, robust optimization, gradient and subgradient methods, splitting techniques, and second-order methods. Many of these techniques draw inspiration from other fields, including operations research, theoretical computer science, and subfields of optimization. The book will enrich the ongoing cross-fertilization between the machine learning community and these other fields, and within the broader optimization community.
