The Human Brain in Dissection will significantly update the previous edition published in 1988. The last 20 years have seen a significant shift in the way that neuroanatomy is taught in both undergraduate and graduate neuroscience courses, as well as doctorate courses: not only has the time allocated for these courses been reduced, but the methodologies for teaching have become more focused and specific due to these time constraints. The Human Brain in Dissection, Third Edition will provide detailed features of the human brain with the above limitations in mind. 50 new plates will be added to the existing 123 in order to permit the student to see all salient structures and to visualize microscopic structures of the brain stem and spinal cord. Each chapter will cover a specific area of the human brain in such a way that each chapter can be taught in one two-hour neuroanatomy course. New to this edition is the inclusion of a section in each chapter on clinically relevant examples. Each chapter will also include a specific laboratory exercise. And finally, the author has included a question and answer section that is relevant to the USMLE, as well as recommended readings, neither of which were included in the previous editions. This new edition of The Human Brain in Dissection will allow the student to: understand basic principles of cellular neuroscience; learn gross and microscopic anatomy of the central nervous system (Brain, brainstem, and spinal cord); relate the anatomy of central neural pathways to specific functional systems; be able to localize and name a CNS lesion when presented with neurological symptoms, and appreciate higher cortical functions and how they relate to the practice of neurology. neuroscience

The "functional" in the title of this book not only reflects my personal bias about neuroanatomy in brain research, it is also the gist of many chapters which describe sophisticated ways to resolve structures and interpret them as dynamic entities. Examples are: the visualization of functionally identified brain areas or neurons by activity staining or intracellular dye-iontophoresis; the resolution of synaptic connections between physiologically identified nerve cells; and the biochemical identification of specific neurons (their peptides and transmitters) by histo- and immunocytochemistry. I personally view the nervous system as an organ whose parts, continuously exchanging messages, arrive at their decisions by the cooperative phenomenon of consensus and debate. This view is, admittedly, based on my own experience of looking at myriads of nerve cells and their connections rather than studying animal behaviour or theorizing. Numerous structural studies have demonstrated that interneurons in the brain must receive hundreds of thousands of synapses. Many neurons receive inputs from several different sensory areas: each input conveys a message about the external world and possibly also about past events which are stored within the central nervous system. Whether an interneuron responds to a certain combination of inputs may be, literally, a matter of debate whose outcome is decided at the post synaptic membrane. A nerve cell responding to an overriding command is possibly a rare event.
